I enumerated the website using gobuster and dirsearch and found an extension called cgi-bin. cgi-bin is a directory that contains compiled script files. Any files in it is treated as programs and is run by the server instead of being displayed normally. I used the shellshock module in meterpreter to get a reverse shell, and then saw that user had permissions to run perl as root. So, I ran sudo perl -e 'exec "/bin/sh";' to get root.
